

- a) The pivot is chosen by line 1 of RANDOMIZED-PARTITION, through randomly selecting a number from  $p$  to  $r$ . Therefore, each element is chosen with equal probability, i.e.  $1/n$ .

$$\mathbb{E}[X_i] = \Pr(i\text{th smallest element is chosen as the pivot}) = 1/n$$

- b) The events  $\{i\text{th smallest element is chosen as the pivot}\}$  for different  $i$ 's are disjoint, i.e. if  $p$ th smallest element has been chosen as the pivot, then  $q$ th smallest element cannot be the pivot, and the probability of their union is 1, i.e. one of them has to happen. When  $X_q = 1$ , i.e. the  $q$ th smallest element has been chosen as the pivot, we have

$$T(n) = T(q-1) + T(n-q) + \Theta(n).$$

Therefore, we have

$$T(n) = \sum_{q=1}^n X_q(T(q-1) + T(n-q) + \Theta(n)),$$

and therefore

$$\mathbb{E}[T(n)] = \mathbb{E}\left[\sum_{q=1}^n X_q(T(q-1) + T(n-q) + \Theta(n))\right]$$

- c)  $\mathbb{E}[T(n)]$

$$= \mathbb{E}[\sum_{q=1}^n X_q(T(q-1) + T(n-q) + \Theta(n))]$$

$$= \sum_{q=1}^n \mathbb{E}[X_q(T(q-1) + T(n-q) + \Theta(n))], \text{ by linearity of } \mathbb{E} \text{ operator}$$

we notice that  $X_q$  only depends on choice of this pivot, and  $(T(q-1) + T(n-q) + \Theta(n))$  does not depend on choice of this pivot, and therefore, they are independent, and therefore we have:

$$= \sum_{q=1}^n \mathbb{E}[X_q] \mathbb{E}[T(q-1) + T(n-q) + \Theta(n)]$$

$$= \sum_{q=1}^n \frac{1}{n} \mathbb{E}[T(q-1) + T(n-q) + \Theta(n)]$$

$$= \frac{1}{n} \sum_{q=1}^n \mathbb{E}[T(q-1)] + \mathbb{E}[T(n-q)] + \Theta(n), \text{ by linearity of } \mathbb{E}$$

we notice that the term corresponding to  $q=k$  and  $q=n+1-k$  are identical, just in reverse order, and that if  $n$  is odd, then for  $q = \frac{n+1}{2}$ ,  $\mathbb{E}[T(q-1)]$  and  $\mathbb{E}[T(n-q)]$  are identical, therefore, by a change in the order of the summation, we have

$$= \frac{1}{n} \sum_{q=1}^n 2\mathbb{E}[T(q-1)] + \Theta(n)$$

$$= \frac{2}{n} \sum_{q=1}^n \mathbb{E}[T(q-1)] + \Theta(n)$$

since  $T(1) = T(0) = \Theta(1)$  are ignorable, by a change of variable  $q \rightarrow q-1$ , we have

$$= \frac{2}{n} \sum_{q=2}^{n-1} \mathbb{E}[T(q)] + \Theta(n)$$

- d)  $\sum_{k=2}^{n-1} k \lg k$

$$= \sum_{k=1}^{n-1} k \lg k$$

$$\begin{aligned}
&= \sum_{k=1}^{\lceil \frac{n}{2} \rceil - 1} k \lg k + \sum_{k=\lceil \frac{n}{2} \rceil}^{n-1} k \lg k \\
&\leq \sum_{k=1}^{\lceil \frac{n}{2} \rceil - 1} k \lg \frac{n}{2} + \sum_{k=\lceil \frac{n}{2} \rceil}^{n-1} k \lg n \\
&= \sum_{k=1}^{\lceil \frac{n}{2} \rceil - 1} k(-1 + \lg n) + \sum_{k=\lceil \frac{n}{2} \rceil}^{n-1} k \lg n \\
&= \lg n \sum_{k=1}^{n-1} k - \sum_{k=1}^{\lceil \frac{n}{2} \rceil - 1} k \\
&\leq \frac{n^2 - n}{2} \lg n - \frac{\frac{n}{2}(\frac{n}{2} - 1)}{2} \\
&\leq \frac{1}{2} n^2 \lg n - \frac{1}{8} n^2 + \frac{n}{2} \left( \frac{1}{2} - \lg n \right) \\
&\leq \frac{1}{2} n^2 \lg n - \frac{1}{8} n^2, \text{ since } n \geq 2 \rightarrow \lg n \geq 1 \rightarrow \frac{1}{2} - \lg n < 0 \rightarrow \frac{n}{2} \left( \frac{1}{2} - \lg n \right) < 0
\end{aligned}$$

e) We first notice that

$$\mathbb{E}[T(n)] = \frac{2}{n} \sum_{q=2}^{n-1} (\mathbb{E}[T(q)] + \Theta(n)) = \Theta(n) + \frac{2}{n} \sum_{q=2}^{n-1} \mathbb{E}[T(q)]$$

We assume  $\Theta(n)$  in the equation above means  $c_1 n \leq \Theta(n) \leq c_2 n$ .

We first prove  $\mathbb{E}[T(n)] \in O(n \lg n)$ , by finding  $a$ , s.t.  $\forall n \geq 2, \mathbb{E}[T(n)] \leq a n \lg n$ .

We first cover the base cases, i.e. select  $a$  large enough s.t.  $\mathbb{E}[T(2)] \leq a 2 \lg 2$ .

We then assume  $\mathbb{E}[T(k)] \leq a k \lg k$ , then, for all  $2 \leq k < n$ .

$$\frac{2}{n} \sum_{q=2}^{n-1} \mathbb{E}[T(q)] \leq \frac{2}{n} \sum_{q=2}^{n-1} a q \lg q \leq \frac{2a}{n} \left( \frac{1}{2} n^2 \lg n - \frac{1}{8} n^2 \right) \leq a n \lg n - \frac{a}{4} n^2$$

$$\mathbb{E}[T(n)] = \Theta(n) + \frac{2}{n} \sum_{q=2}^{n-1} \mathbb{E}[T(q)] \leq \Theta(n) + a n \lg n - \frac{a}{4} n^2 \leq a n \lg n + c_2 n - \frac{a}{4} n^2 \quad (*)$$

We let  $a > 4c_2$ , then we have

$$n \geq 1 \rightarrow n^2 > n \rightarrow a n^2 > 4c_2 n \rightarrow c_2 n - \frac{a}{4} n^2 < 0 \rightarrow (*) < a n \lg n$$

In conclusion, we have successfully found  $a = \max\left(\frac{\mathbb{E}[T(2)]}{2 \lg 2}, 4c_2\right) + 1$ .

We then prove  $\mathbb{E}[T(n)] \in \Omega(n \lg n)$ , by finding  $b$ , s.t.  $\forall n \geq 2, \mathbb{E}[T(n)] \geq b n \lg n$ .

We first find a lower bound for  $\sum_{k=2}^{n-1} k \lg k$ .
